

## 5 V, 3 A Current-Mode Constant On-Time Synchronous Buck Regulator

### DESCRIPTION

The SiP12107 is a high frequency current-mode constant on-time (CM-COT) synchronous buck regulator with integrated high-side and low-side power MOSFETs. Its power stage is capable of supplying 3 A continuous current at 4 MHz switching frequency. This regulator produces an adjustable output voltage down to 0.6 V from 2.8 V to 5.5 V input rail to accommodate a variety of applications, including computing, consumer electronics, telecom, and industrial.

SiP12107's CM-COT architecture delivers ultra-fast transient response with minimum output capacitance and tight ripple regulation at very light load. No ESR or external ESR network is required for loop stability purpose. The device also incorporates a power saving scheme that significantly increases light load efficiency.

The regulator integrates a full protection feature set, including output overvoltage protection (OVP), output under voltage protection (UVP) and thermal shutdown (OTP). It also has UVLO for input rail and internal soft-start ramp.

The SiP12107 is available in lead (Pb)-free power enhanced MLP-16L package in 3 mm x 3 mm dimension.

### FEATURES

- **Halogen-free According to IEC 61249-2-21 Definition**
- 2.8 V to 5.5 V input voltage
- Adjustable output voltage down to 0.6 V
- 3 A continuous output current
- Programmable switching frequency up to 4 MHz
- 95 % peak efficiency
- Supports all ceramic capacitors No external ESR required
- Ultrafast transient response
- Selectable power saving mode or force current mode
- $\pm 1\%$  accuracy
- Pulse-by-pulse current limit
- Scalable with SiP12108 - 5A
- Fully protected with OTP, SCP, UVP, OVP
- P<sub>Good</sub> Indicator
- Compliant to RoHS Directive 2011/65/EU

**RoHS**  
COMPLIANT  
HALOGEN  
**FREE**

### APPLICATIONS

- Notebook computers
- Desktop PCs and servers
- Handheld devices
- POLs for telecom
- Consumer electronics
- Industrial and automation

### TYPICAL APPLICATION CIRCUIT AND PACKAGE OPTIONS

## OPERATIONAL DESCRIPTION

### Device Overview

SiP12107 is a high-efficiency monolithic synchronous buck regulator capable of delivering up to 3 A continuous current. The device has programmable switching frequency up to 4 MHz. The control scheme is based on current-mode constant-on-time architecture, which delivers fast transient response and minimizes external components. Thanks to the internal current ramp information, no high-ESR output bulk or virtual ESR network is required for the loop stability. This device also incorporates Power-Saving feature by enabling diode emulation mode and frequency foldback as load decrease.

SiP12107 has a full set of protection and monitoring features:

- Over current protection in pulse-by-pulse mode
- Output over voltage protection
- Output under voltage protection with device latch
- Over temperature protection with hysteresis
- Dedicated enable pin for easy power sequencing
- Power Good open drain output

This device is available in MLPQ 3 x 3-16L package to deliver high power density and minimize PCB area.

### Power Stage

SiP12107 integrates a high-performance power stage with a  $\sim 64 \text{ m}\Omega$  p-channel MOSFET and a  $\sim 33 \text{ m}\Omega$  n-channel MOSFET. The MOSFETs are optimized to achieve 95 % efficiency at 2 MHz switching frequency.

The power input voltage ( $V_{IN}$ ) can go up to 5.5 V and down as low as 2.8 V for the power conversion. The logic bias voltage ( $AV_{IN}$ ) ranges from 2.8 V to 5.5 V.

### PWM Control Mechanism

SiP12107 employs a state-of-the-art current-mode COT control mechanism. During steady-state operation, output voltage is compared with internal reference (0.6 V typ.) and the amplified error signal ( $V_{COMP}$ ) is generated on the COMP pin. In the meantime, inductor valley current is sensed, and its slope ( $I_{sense}$ ) is converted into a voltage signal ( $V_{current}$ ) to be compared with  $V_{COMP}$ . Once  $V_{current}$  is lower than  $V_{COMP}$ , a single shot on-time is generated for a fixed time programmed by the external  $R_{ON}$ . Figure 4 illustrates the basic block diagram for CM-COT architecture and figure 5 demonstrates the basic operational principle:

Fig. 4 - CM-COT Block Diagram

**Fig. 5 - CM-COT Operational Principle**

The following equation illustrates the relationship between on-time,  $V_{IN}$ ,  $V_{OUT}$  and  $R_{ON}$  value:

$$T_{ON} = R_{ON} \times K \times \frac{V_{OUT}}{V_{IN}}, \text{ where } K = 9.6 \times 10^{-12} \text{ a constant set internally}$$

Once on-time is set, the pseudo constant frequency is then determined by the following equation:

$$f_{sw} = \frac{D}{T_{ON}} = \frac{\frac{V_{OUT}}{V_{IN}}}{\frac{V_{OUT}}{V_{IN}} \times R_{ON} \times K} = \frac{1}{R_{ON} \times K}$$

### Loop Stability and Compensator Design

Due to the nature of current mode control, a simple RC network (type II compensator) is required between COMP and  $A_{GND}$  for loop stability and transient response purpose. General concept of this loop design is to introduce a single zero through the compensator to determine the crossover frequency of overall close loop system.

The overall loop can be broken down into following segments.

Output feedback divider transfer function  $H_{fb}$ :

$$H_{fb} = \frac{R_{fb2}}{R_{fb1} \times R_{fb2}}$$

Voltage compensator transfer function  $G_{COMP}$  (s):

$$G_{COMP}(s) = \frac{R_O \times (1 + sC_{COMP}R_{COMP})}{(1 + sR_OC_{COMP})} gm$$

Modulator transfer function  $H_{mod}$  (s):

$$H_{mod}(s) = \frac{1}{AV_1 \times R_{DS(on)}} \times \frac{R_{load} \times (1 + sC_O R_{ESR})}{(1 + sC_O R_{load})}$$

The complete loop transfer function is given by:

$$H_{mod}(s) = \frac{R_{fb2}}{R_{fb1} \times R_{fb2}} \times \frac{R_O \times (1 + sC_{COMP}R_{COMP})}{(1 + sR_OC_{COMP})} gm \times \frac{1}{AV_1 \times R_{DS(on)}} \times \frac{R_{load} \times (1 + sC_O R_{ESR})}{(1 + sC_O R_{load})}$$

#### When:

$C_{COMP}$  = Compensation capacitor

$R_{COMP}$  = Compensation resistor

$gm$  = Error amplifier transconductance

$R_{load}$  = Load resistance

$C_O$  = Output capacitor

$R_{DS(on)}$  = LS switch resistance

$R_{fb1}$  = Feedback resistor connect to LX

$R_{fb2}$  = Feedback resistor connect to ground

$R_O$  = Output impedance of error amplifier = 20 M $\Omega$

$AV_1$  = Voltage to current gain = 3

### Power-Saving Mode Operation

To further improve efficiency at light-load condition, SiP12107 provides a set of innovative implementations to eliminate LS recirculating current and switching losses. The internal Zero Crossing Detector (ZCD) monitors LX node voltage to determine when inductor current starts to flow negatively. In power saving mode (PSM), as soon as inductor valley current crosses zero, the device first deploys diode emulation mode by turning off LS FET. If load further decreases, switching frequency is further reduced

proportional to load condition to save switching losses while keeping output ripple within tolerance. The switching frequency is set by the controller to maintain regulation. At zero load this frequency can go as low as hundreds of Hz.

Whenever fixed frequency PWM operation is required over the entire load span, power saving mode feature can be disabled by connecting AUTO pin to  $V_{IN}$  or  $AV_{IN}$ .

## OUTPUT MONITORING AND PROTECTION FEATURES

### Output Over-Current Protection (OCP)

SiP12107 has pulse-by-pulse over-current limit control. The inductor valley current is monitored during LS FET turn-on period through  $R_{DS(on)}$  sensing. After a pre-defined time, the valley current is compared with internal threshold (5 A typ.) to determine the threshold for OCP. If monitored current is higher than threshold, HS turn-on pulse is skipped and LS FET is kept on until the valley current returns below OCP limit.

In the severe over-current condition, pulse-by-pulse current limit eventually triggers output under-voltage protection (UVP), which latches the device off to prevent catastrophic thermal-related failure. UVP is described in the next section.

OCP is enabled immediately after  $AV_{IN}$  passes UVLO level.

Figure 6 illustrates the OCP operation.

**Fig. 6 - Over-Current Protection Illustration**

### Output Under-Voltage Protection (UVP)

UVP is implemented by monitoring output through  $V_{FB}$  pin. Once the voltage level at  $V_{FB}$  is below 0.45 V for more than 20  $\mu$ s, then UVP event is recognized and both HS and LS MOSFETs are turned off. UVP latches the device off until either  $AV_{IN}$  or EN is recycled.

UVP is only active after the completion of soft-start sequence.

### Output Over-Voltage Protection (OVP)

For OVP implementation, output is monitored through FB pin. After soft-start, if the voltage level at FB is above 20 % (typ.), OVP is triggered with HS FET turning off and LS FET turning on immediately to discharge the output. Normal operation is resumed once FB voltage drops back to 0.6 V.

OVP is active immediately after  $AV_{IN}$  passes UVLO level.

### Over-Temperature Protection (OTP)

SiP12107 has internal thermal monitor block that turns off both HS and LS FETs when junction temperature is above 160  $^{\circ}$ C (typ.). A hysteresis of 30  $^{\circ}$ C is implemented, so when junction temperature drops below 130  $^{\circ}$ C, the device restarts by initiating the soft-start sequence again.

### Soft Startup

SiP12107 deploys an internally regulated soft-start sequence to realize a monotonic startup ramp without any output overshoot. Once  $AV_{IN}$  is above UVLO level (2.55 V typ.). Both the reference and  $V_{OUT}$  will ramp up slowly to regulation in 1 ms (typ.) with the reference going from 0 V to 0.6 V and  $V_{OUT}$  rising monotonically to the programmed output voltage.

During soft-start period, OCP is activated. OVP and short-circuit protection are not active until soft-start is complete.

### Pre-bias Startup

In case of pre-bias startup, output is monitored through FB pin. If the sensed voltage on FB is higher than the internal reference ramp value, control logic prevents HS and LS FET from switching to avoid negative output voltage spike and excessive current sinking through LS FET.

### Power Good (PG)

SiP12107's Power Good is an open-drain output. Pull PG pin high up to 5 V through a 10K resistor to use this signal. Power Good window is shown in the below diagram. If voltage level on FB pin is out of this window, PG signal is de-asserted by pulling down to GND.

Fig. 7 - PG Window and Timing Diagram

### DESIGN PROCEDURE

The design process of the SiP12107 is quite straight forward. Only few passive components such as output capacitors, inductor and  $R_{ON}$  resistor need to be selected.

The following paragraph describes the selection procedure for these peripheral components for a given operating conditions.

In the next example the following definitions apply:

$V_{INmax}$ : the highest specified input voltage

$V_{INmin}$ : the minimum effective input voltage subject to voltage drops due to connectors, fuses, switches, and PCB traces

There are two values of load current to evaluate - continuous load current and peak load current.

Continuous load current relates to thermal stress considerations which drive the selection of the inductor and input capacitors.

Peak load current determines instantaneous component stresses and filtering requirements such as inductor saturation, output capacitors, and design of the current limit circuit.

The following specifications are used in this design:

- $V_{IN} = 3.3 \text{ V} \pm 10 \%$
- $V_{OUT} = 1.2 \text{ V} \pm 1 \%$
- $F_{SW} = 1 \text{ MHz}$
- Load = 3 A maximum

### Setting Switching Frequency

Selection of the switching frequency requires making a trade-off between the size and cost of the external filter components (inductor and output capacitor) and the power conversion efficiency. The desired switching frequency, 1 MHz was chosen based on optimizing efficiency while maintaining a small footprint and minimizing component cost.

In order to set the design for 1 MHz switching frequency, ( $R_{ON}$ ) resistor which determines the on-time (indirectly setting the frequency) needs to be calculated using the following equation.

$$R_{ON} = \frac{1}{F_{SW} \times K} = \frac{1}{1 \times 10^6 \times 9.6 \times 10^{-12}} \cong 105 \text{ k}\Omega$$

## INDUCTOR SELECTION

In order to determine the inductance, the ripple current must first be defined. Cost, PCB size, output ripple, and efficiency are all used in the selection process. Low inductor values result in smaller size and allow faster transient performance but create higher ripple current which can reduce efficiency. Higher inductor values will reduce the ripple current while compromising the efficiency (higher DCR) and transient response.

The ripple current will also set the boundary for power-save operation. The switcher will typically enter power-save mode when the load current decreases to 1/2 of the ripple current. For example, if ripple current is 1 A then power-save operation will typically start at loads approaching 0.5 A. Alternatively, if ripple current is set at 40 % of maximum load current, then power-save will start for loads less than ~ 20 % of maximum current.

Setting the ripple current 20 % to 50 % of the maximum load current provides an optimal trade-off of the areas mentioned above.

The equation for determining inductance is shown next.

### Example

In this example, the inductor ripple current is set equal to 30 % of the maximum load current. Thus ripple current will be 30 % x 3 A or 0.9 A. To find the minimum inductance needed, use the  $V_{IN}$  and  $T_{ON}$  values that correspond to  $V_{INmax}$ .

$$L = (V_{IN} - V_{OUT}) \times \frac{T_{ON}}{\Delta i}$$

Plugging numbers into the above equation we get

$$L = (3.63 \text{ V} - 1.2 \text{ V}) \times \frac{330 \times 10^{-9} \text{ s}}{0.9 \text{ A}} = 0.891 \mu\text{H}$$

A slightly larger value of 1  $\mu\text{H}$  is selected which is a standard value. This will decrease the maximum ripple current by 10 %. Note that the inductor must be rated for the maximum DC load current plus 1/2 of the ripple current. The actual ripple current using the chosen 1  $\mu\text{H}$  inductor comes out to be.

$$\Delta i = (3.63 \text{ V} - 1.2 \text{ V}) \times \frac{330 \text{ ns}}{1 \mu\text{H}} = 0.8 \text{ A}$$

### Output Capacitance Calculation

The output capacitance is usually chosen to meet transient requirements. A worst-case load release, from maximum load to no load at the exact moment when inductor current is at the peak, determines the required capacitance. If the load release is instantaneous (load changes from maximum to zero in  $< 1/F_{SW}$   $\mu\text{s}$ ), the output capacitor must absorb all the inductor's stored energy. This will approximately cause a peak voltage on the capacitor according to the following equation.

$$C_{OUTmin.} = \frac{L \times \left( I_{OUT} + \frac{1}{2} \times I_{RIPPLEmax.} \right)^2}{(V_{peak})^2 - (V_{OUT})^2}$$

Assuming a peak voltage  $V_{PEAK}$  of 1.3 V (100 mV rise upon load release), and a 3 A load release, the required capacitance is shown by the next equation.

$$C_{OUTmin.} = \frac{1 \mu\text{H} \times (3 \text{ A} + 0.5 \times (81 \text{ A}))^2}{(1.3 \text{ V})^2 - (1.2 \text{ V})^2} = 46.37 \mu\text{F}$$

If the load release is relatively slow, the output capacitance can be reduced. Using MLCC ceramic capacitors we will use 3 x 22  $\mu\text{F}$  or 66  $\mu\text{F}$  as the total output capacitance.

## STABILITY CONSIDERATIONS

Using the output capacitance as a starting point for compensation values. Then, taking Bode plots and transient response measurements we can fine tune the compensation values.

Setting the crossover frequency to 1/5 of the switching frequency:

$$F_0 = F_{sw}/5 = 1 \text{ MHz}/5 = 200 \text{ kHz}$$

Setting the compensation zero at 1/5 to 1/10 the crossover frequency for the phase boost:

$$F_z = \frac{1}{2\pi \times R_C \times C_C} = \frac{F_0}{5}$$

Setting  $C_C = 1 \text{ nF}$  and solve for  $R_C$

$$R_C = \frac{5}{2\pi \times C_C \times F_0} = \frac{5}{2\pi \times 1 \text{ nF} \times 200\text{K}} = 4\text{K}$$

## SWITCHING FREQUENCY VARIATIONS

The switching frequency variation in COT can be mainly attributed to the increase in conduction losses as the load increases. The on time is "ideally constant" so the controller must account for losses by reducing the off time which increases the overall duty cycle. Hence the  $F_{SW}$  will tend to increase with load.

In power save mode (PSM) the IC will run in pulse skip mode at light loads. As the load increases the  $F_{SW}$  will increase until it reaches the nominal set  $F_{SW}$ . This transition occurs approximately when the load reaches to 20 % of the full load current.

Vishay Siliconix maintains worldwide manufacturing capability. Products may be manufactured at one of several qualified locations. Reliability data for Silicon Technology and Package Reliability represent a composite of all qualified locations. For related documents such as package/tape drawings, part marking, and reliability data, see [www.vishay.com/ppg?63395](http://www.vishay.com/ppg?63395).

## **Disclaimer**

ALL PRODUCT, PRODUCT SPECIFICATIONS AND DATA ARE SUBJECT TO CHANGE WITHOUT NOTICE TO IMPROVE RELIABILITY, FUNCTION OR DESIGN OR OTHERWISE.

Vishay Intertechnology, Inc., its affiliates, agents, and employees, and all persons acting on its or their behalf (collectively, "Vishay"), disclaim any and all liability for any errors, inaccuracies or incompleteness contained in any datasheet or in any other disclosure relating to any product.

Vishay makes no warranty, representation or guarantee regarding the suitability of the products for any particular purpose or the continuing production of any product. To the maximum extent permitted by applicable law, Vishay disclaims (i) any and all liability arising out of the application or use of any product, (ii) any and all liability, including without limitation special, consequential or incidental damages, and (iii) any and all implied warranties, including warranties of fitness for particular purpose, non-infringement and merchantability.

Statements regarding the suitability of products for certain types of applications are based on Vishay's knowledge of typical requirements that are often placed on Vishay products in generic applications. Such statements are not binding statements about the suitability of products for a particular application. It is the customer's responsibility to validate that a particular product with the properties described in the product specification is suitable for use in a particular application. Parameters provided in datasheets and / or specifications may vary in different applications and performance may vary over time. All operating parameters, including typical parameters, must be validated for each customer application by the customer's technical experts. Product specifications do not expand or otherwise modify Vishay's terms and conditions of purchase, including but not limited to the warranty expressed therein.

Except as expressly indicated in writing, Vishay products are not designed for use in medical, life-saving, or life-sustaining applications or for any other application in which the failure of the Vishay product could result in personal injury or death. Customers using or selling Vishay products not expressly indicated for use in such applications do so at their own risk. Please contact authorized Vishay personnel to obtain written terms and conditions regarding products designed for such applications.

No license, express or implied, by estoppel or otherwise, to any intellectual property rights is granted by this document or by any conduct of Vishay. Product names and markings noted herein may be trademarks of their respective owners.
