

2-Mbit (64K x 32) Pipelined SRAM with NoBL™ Architecture

Features

- Pin compatible and functionally equivalent to ZBT™ devices
- Internally self-timed output buffer control to eliminate the need to use OE
- Byte Write capability
- 64K x 32 common I/O architecture
- 3.3V core power supply
- 3.3V/2.5V I/O operation
- Fast clock-to-output times
 - 3.5 ns (for 166-MHz device)
 - 4.0 ns (for 133-MHz device)
- Clock Enable (CEN) pin to suspend operation
- Synchronous self-timed write
- Asynchronous output enable (OE)
- Offered in Lead-Free JEDEC-standard 100-pin TQFP package
- Burst Capability—linear or interleaved burst order
- “ZZ” Sleep mode option

Functional Description^[1]

The CY7C1334H is a 3.3V/2.5V, 64K x 32 synchronous-pipelined Burst SRAM designed specifically to support unlimited true back-to-back Read/Write operations without the insertion of wait states. The CY7C1334H is equipped with the advanced No Bus Latency™ (NoBL™) logic required to enable consecutive Read/Write operations with data being transferred on every clock cycle. This feature dramatically improves the throughput of the SRAM, especially in systems that require frequent Write/Read transitions.

All synchronous inputs pass through input registers controlled by the rising edge of the clock. All data outputs pass through output registers controlled by the rising edge of the clock. The clock input is qualified by the Clock Enable (CEN) signal, which, when deasserted, suspends operation and extends the previous clock cycle. Maximum access delay from the clock rise is 3.5 ns (166-MHz device)

Write operations are controlled by the four Byte Write Select ($\overline{BW}_{[A:D]}$) and a Write Enable (WE) input. All writes are conducted with on-chip synchronous self-timed write circuitry.

Three synchronous Chip Enables (\overline{CE}_1 , \overline{CE}_2 , \overline{CE}_3) and an asynchronous Output Enable (OE) provide for easy bank selection and output tri-state control. In order to avoid bus contention, the output drivers are synchronously tri-stated during the data portion of a write sequence.

Note:

1. For best-practices recommendations, please refer to the Cypress application note *System Design Guidelines* on www.cypress.com.

Selection Guide

	166 MHz	133 MHz	Unit
Maximum Access Time (t_{CO})	3.5	4.0	ns
Maximum Operating Current (I_{DD})	240	225	mA
Maximum CMOS Standby Current	40	40	mA

Pin Configuration

100-Pin TQFP Pinout

Pin Definitions

Name	I/O	Description
A0, A1, A	Input-Synchronous	Address Inputs used to select one of the 64K address locations. Sampled at the rising edge of the CLK. A _[1:0] are fed to the two-bit burst counter.
BW _[A:D]	Input-Synchronous	Byte Write Inputs, active LOW. Qualified with \overline{WE} to conduct writes to the SRAM. Sampled on the rising edge of CLK.
\overline{WE}	Input-Synchronous	Write Enable Input, active LOW. Sampled on the rising edge of CLK if \overline{CEN} is active LOW. This signal must be asserted LOW to initiate a Write sequence.
$\overline{ADV/LD}$	Input-Synchronous	Advance/Load Input. Used to advance the on-chip address counter or load a new address. When HIGH (and \overline{CEN} is asserted LOW) the internal burst counter is advanced. When LOW, a new address can be loaded into the device for an access. After being deselected, $\overline{ADV/LD}$ should be driven LOW in order to load a new address.
CLK	Input-Clock	Clock Input. Used to capture all synchronous inputs to the device. CLK is qualified with \overline{CEN} . CLK is only recognized if \overline{CEN} is active LOW.
CE ₁	Input-Synchronous	Chip Enable 1 Input, active LOW. Sampled on the rising edge of CLK. Used in conjunction with CE ₂ and CE ₃ to select/deselect the device.
CE ₂	Input-Synchronous	Chip Enable 2 Input, active HIGH. Sampled on the rising edge of CLK. Used in conjunction with CE ₁ and CE ₃ to select/deselect the device.
$\overline{CE_3}$	Input-Synchronous	Chip Enable 3 Input, active LOW. Sampled on the rising edge of CLK. Used in conjunction with CE ₁ and CE ₂ to select/deselect the device.
\overline{OE}	Input-Asynchronous	Output Enable, asynchronous input, active LOW. Combined with the synchronous logic block inside the device to control the direction of the I/O pins. When LOW, the I/O pins are allowed to behave as outputs. When deasserted HIGH, I/O pins are tri-stated, and act as input data pins. \overline{OE} is masked during the data portion of a write sequence, during the first clock when emerging from a deselected state, when the device has been deselected.
\overline{CEN}	Input-Synchronous	Clock Enable Input, active LOW. When asserted LOW the Clock signal is recognized by the SRAM. When deasserted HIGH the Clock signal is masked. Since deasserting \overline{CEN} does not deselect the device, \overline{CEN} can be used to extend the previous cycle when required.
ZZ	Input-Asynchronous	ZZ “sleep” Input. This active HIGH input places the device in a non-time critical “sleep” condition with data integrity preserved. During normal operation, this pin can be connected to V _{SS} or left floating.
DQs	I/O-Synchronous	Bidirectional Data I/O Lines. As inputs, they feed into an on-chip data register that is triggered by the rising edge of CLK. As outputs, they deliver the data contained in the memory location specified by A _[16:0] during the clock rise of the read cycle. The direction of the pins is controlled by \overline{OE} and the internal control logic. When \overline{OE} is asserted LOW, the pins can behave as outputs. When HIGH, DQ _s are placed in a tri-state condition. The outputs are automatically tri-stated during the data portion of a write sequence, during the first clock when emerging from a deselected state, and when the device is deselected, regardless of the state of \overline{OE} .
MODE	Input Strap pin	Mode Input. Selects the burst order of the device. When tied to Gnd selects linear burst sequence. When tied to V _{DD} or left floating selects interleaved burst sequence.
V _{DD}	Power Supply	Power supply inputs to the core of the device.
V _{DDQ}	I/O Power Supply	Power supply for the I/O circuitry.
V _{SS}	Ground	Ground for the device.
V _{SSQ}	I/O Ground	Ground for the I/O circuitry. Should be connected to the ground of the system
NC		No Connects. Not internally connected to the die. 4M, 9M, 18M, 72M, 144M, 288M, 576M and 1G are address expansion pins and are not internally connected to the die.

Functional Overview

The CY7C1334H is a synchronous-pipelined Burst SRAM designed specifically to eliminate wait states during Write/Read transitions. All synchronous inputs pass through input registers controlled by the rising edge of the clock. The clock signal is qualified with the Clock Enable input signal (CEN). If CEN is HIGH, the clock signal is not recognized and all internal states are maintained. All synchronous operations are qualified with $\overline{\text{CEN}}$. All data outputs pass through output registers controlled by the rising edge of the clock. Maximum access delay from the clock rise (t_{CO}) is 3.5 ns (166-MHz device).

Accesses can be initiated by asserting all three Chip Enables ($\overline{\text{CE}}_1$, $\overline{\text{CE}}_2$, $\overline{\text{CE}}_3$) active at the rising edge of the clock. If Clock Enable (CEN) is active LOW and ADV/LD is asserted LOW, the address presented to the device will be latched. The access can either be a Read or Write operation, depending on the status of the Write Enable (WE). $\text{BW}_{[\text{A:D}]}$ can be used to conduct Byte Write operations.

Write operations are qualified by the Write Enable ($\overline{\text{WE}}$). All writes are simplified with on-chip synchronous self-timed write circuitry.

Three synchronous Chip Enables ($\overline{\text{CE}}_1$, $\overline{\text{CE}}_2$, $\overline{\text{CE}}_3$) and an asynchronous Output Enable ($\overline{\text{OE}}$) simplify depth expansion. All operations (Reads, Writes, and Deselects) are pipelined. ADV/LD should be driven LOW once the device has been deselected in order to load a new address for the next operation.

Single Read Accesses

A read access is initiated when the following conditions are satisfied at clock rise: (1) CEN is asserted LOW, (2) $\overline{\text{CE}}_1$, $\overline{\text{CE}}_2$, and $\overline{\text{CE}}_3$ are ALL asserted active, (3) the Write Enable input signal WE is deasserted HIGH, and (4) ADV/LD is asserted LOW. The address presented to the address inputs is latched into the Address Register and presented to the memory core and control logic. The control logic determines that a read access is in progress and allows the requested data to propagate to the input of the output register. At the rising edge of the next clock the requested data is allowed to propagate through the output register and onto the data bus, provided OE is active LOW. After the first clock of the read access the output buffers are controlled by $\overline{\text{OE}}$ and the internal control logic. $\overline{\text{OE}}$ must be driven LOW in order for the device to drive out the requested data. During the second clock, a subsequent operation (Read/Write/Deselect) can be initiated. Deselecting the device is also pipelined. Therefore, when the SRAM is deselected at clock rise by one of the chip enable signals, its output will tri-state following the next clock rise.

Burst Read Accesses

The CY7C1334H has an on-chip burst counter that allows the user the ability to supply a single address and conduct up to four Reads without reasserting the address inputs. ADV/LD must be driven LOW in order to load a new address into the SRAM, as described in the Single Read Access section above. The sequence of the burst counter is determined by the MODE input signal. A LOW input on MODE selects a linear burst mode, a HIGH selects an interleaved burst sequence. Both burst counters use A0 and A1 in the burst sequence, and will wrap around when incremented sufficiently. A HIGH input on ADV/LD will increment the internal burst counter regardless of

the state of Chip Enables inputs or $\overline{\text{WE}}$. $\overline{\text{WE}}$ is latched at the beginning of a burst cycle. Therefore, the type of access (Read or Write) is maintained throughout the burst sequence.

Single Write Accesses

Write accesses are initiated when the following conditions are satisfied at clock rise: (1) CEN is asserted LOW, (2) $\overline{\text{CE}}_1$, $\overline{\text{CE}}_2$, and $\overline{\text{CE}}_3$ are ALL asserted active, and (3) the write signal WE is asserted LOW. The address presented to the address inputs is loaded into the Address Register. The write signals are latched into the Control Logic block.

On the subsequent clock rise the data lines are automatically tri-stated regardless of the state of the $\overline{\text{OE}}$ input signal. This allows the external logic to present the data on DQs and $\text{DQP}_{[\text{A:D}]}$. In addition, the address for the subsequent access (Read/Write/Deselect) is latched into the Address Register (provided the appropriate control signals are asserted).

On the next clock rise the data presented to DQs (or a subset for Byte Write operations, see Write Cycle Description table for details) inputs is latched into the device and the write is complete.

The data written during the Write operation is controlled by $\text{BW}_{[\text{A:D}]}$ signals. The CY7C1334H provides Byte Write capability that is described in the Write Cycle Description table. Asserting the Write Enable input (WE) with the selected Byte Write Select ($\text{BW}_{[\text{A:D}]}$) input will selectively write to only the desired bytes. Bytes not selected during a Byte Write operation will remain unaltered. A synchronous self-timed write mechanism has been provided to simplify the Write operations. Byte write capability has been included in order to greatly simplify Read/Modify/Write sequences, which can be reduced to simple Byte Write operations.

Because the CY7C1334H is a common I/O device, data should not be driven into the device while the outputs are active. The Output Enable (OE) can be deasserted HIGH before presenting data to the DQs. Doing so will tri-state the output drivers. As a safety precaution, DQs are automatically tri-stated during the data portion of a Write cycle, regardless of the state of OE.

Burst Write Accesses

The CY7C1334H has an on-chip burst counter that allows the user the ability to supply a single address and conduct up to four Write operations without reasserting the address inputs. ADV/LD must be driven LOW in order to load the initial address, as described in the Single Write Access section above. When ADV/LD is driven HIGH on the subsequent clock rise, the Chip Enables ($\overline{\text{CE}}_1$, $\overline{\text{CE}}_2$, and $\overline{\text{CE}}_3$) and WE inputs are ignored and the burst counter is incremented. The correct $\text{BW}_{[\text{A:D}]}$ inputs must be driven in each cycle of the burst write in order to write the correct bytes of data.

Sleep Mode

The ZZ input pin is an asynchronous input. Asserting ZZ places the SRAM in a power conservation "sleep" mode. Two clock cycles are required to enter into or exit from this "sleep" mode. While in this mode, data integrity is guaranteed. Accesses pending when entering the "sleep" mode are not considered valid nor is the completion of the operation guaranteed. The device must be deselected prior to entering the "sleep" mode. $\overline{\text{CE}}_1$, $\overline{\text{CE}}_2$, and $\overline{\text{CE}}_3$, must remain inactive for the duration of t_{ZZREC} after the ZZ input returns LOW.

Sleep MODE	None	X	H	X	X	X	X	X	X	Tri-State

Notes:

- X = "Don't Care." H = HIGH, L = LOW. $\overline{\text{CE}}$ stands for ALL Chip Enables active. $\overline{\text{BW}}_x = 0$ signifies at least one Byte Write Select is active, $\overline{\text{BW}}_x = \text{Valid}$ signifies that the desired Byte Write Selects are asserted, see Write Cycle Description table for details.
- Write is defined by $\text{BW}_{[A,D]}$ and $\overline{\text{WE}}$. See Write Cycle Descriptions table.
- When a write cycle is detected, all I/Os are three-stated, even during byte writes.
- The DQ pins are controlled by the current cycle and the $\overline{\text{OE}}$ signal. $\overline{\text{OE}}$ is asynchronous and is not sampled with the clock.
- $\overline{\text{CEN}} = \text{H}$, inserts wait states.
- Device will power-up deselected and the I/Os in a three-state condition, regardless of $\overline{\text{OE}}$.
- $\overline{\text{OE}}$ is asynchronous and is not sampled with the clock rise. It is masked internally during write cycles. During a read cycle DQs and $\text{DQP}_{[A,D]} = \text{Tri-State}$ when $\overline{\text{OE}}$ is inactive or when the device is deselected, and DQs = data when $\overline{\text{OE}}$ is active.

t _{CEH}	Chip Enable Hold after CLK Rise	0.5		0.5		ns

Notes:

12. Test conditions shown in (a), (b) and (c) of AC Test Loads.

13. Timing reference level is 1.5V when V_{DDQ} = 3.3V and 1.25V when V_{DDQ} = 2.5V.

14. This part has a voltage regulator internally; t_{POWER} is the time that the power needs to be supplied above V_{DD} minimum initially before a Read or Write operation can be initiated.

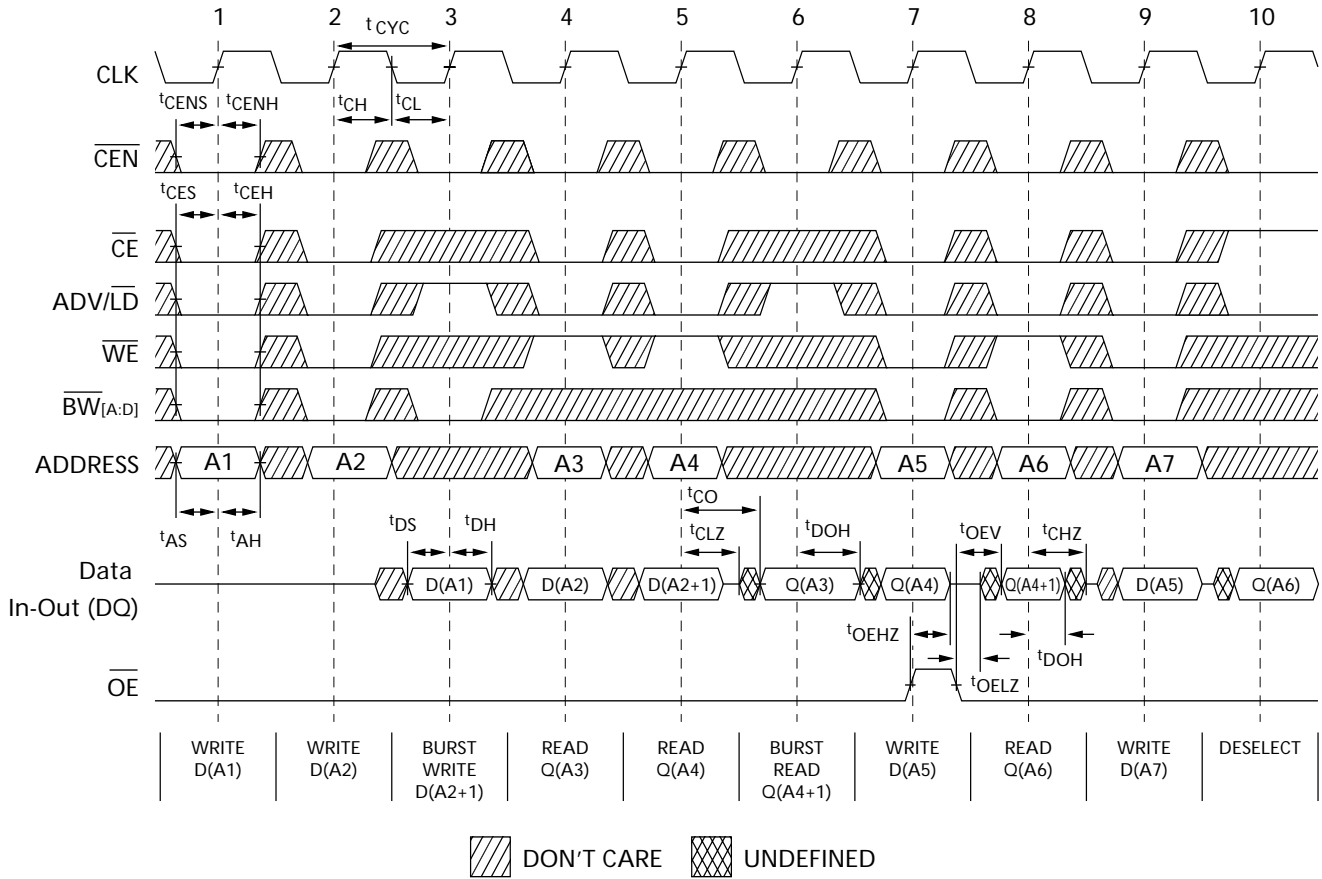

15. t_{CHZ}, t_{CLZ}, t_{OELZ}, and t_{OEHZ} are specified with AC test conditions shown in part (b) of AC Test Loads. Transition is measured ± 200 mV from steady-state voltage.

16. At any given voltage and temperature, t_{OEHZ} is less than t_{OELZ} and t_{CHZ} is less than t_{CLZ} to eliminate bus contention between SRAMs when sharing the same data bus. These specifications do not imply a bus contention condition, but reflect parameters guaranteed over worst case user conditions. Device is designed to achieve Tri-State prior to Low-Z under the same system conditions

17. This parameter is sampled and not 100% tested.

Switching Waveforms

Read/Write Timing^[18, 19, 20]

Notes:

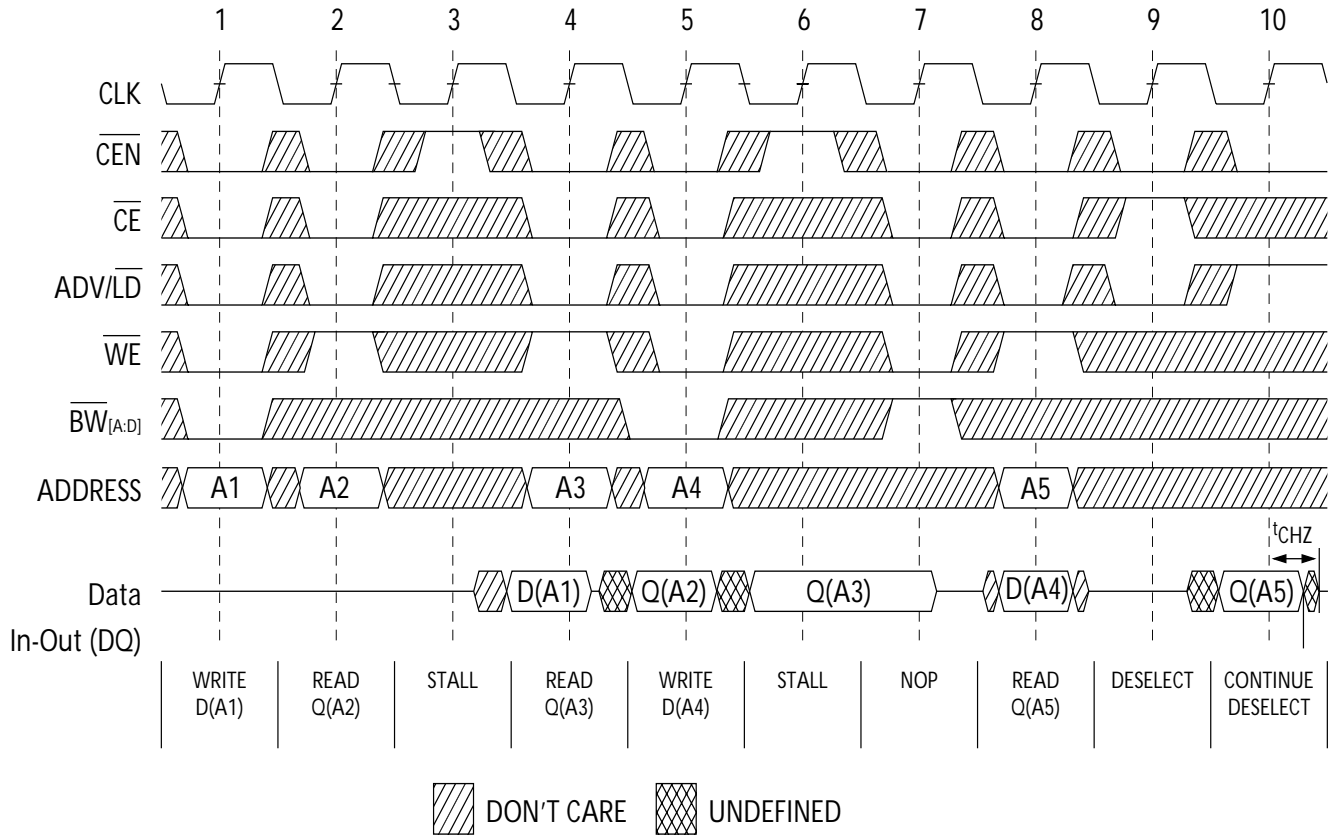

18. For this waveform ZZ is tied LOW.

19. When \overline{CE} is LOW, \overline{CE}_1 is LOW, \overline{CE}_2 is HIGH and \overline{CE}_3 is LOW. When \overline{CE} is HIGH, \overline{CE}_1 is HIGH or \overline{CE}_2 is LOW or \overline{CE}_3 is HIGH.

20. Order of the Burst sequence is determined by the status of the MODE (0 = Linear, 1 = Interleaved). Burst operations are optional.

Switching Waveforms (continued)

NOP, STALL, and Deselect Cycles^[18, 19, 21]

ZZ Mode Timing^[22, 23]

- Notes:**
- 21. The IGNORE CLOCK EDGE or STALL cycle (Clock 3) illustrated $\overline{\text{CEN}}$ being used to create a pause. A write is not performed during this cycle.
 - 22. Device must be deselected when entering ZZ mode. See cycle description table for all possible signal conditions to deselect the device.
 - 23. I/Os are in High-Z when exiting ZZ sleep mode.
